

It's all about Balance:

Using a watershed model to evaluate costs, benefits and trade-offs for Monponsett Ponds watershed

Issues identified in Monponsett Pond Watershed

- EPA Region 1 reached out to towns in the Taunton River watershed to identify those interested in testing new version of EPA watershed management tool (WMOST)
- Cathy Drinan responded on behalf of Monponsett Pond Watershed Workgroup

Water Quantity

- Outflow from pond to Stump Brook does not resemble natural flow regime and does not support fish migration and the downstream ecosystems
- Brockton water diversions reduce volume, and reverse the flow of water between ponds
- High pond elevation can cause flooding when it rains
- Low pond elevation does not support recreational use
- Monponsett Pond towns have water restrictions, no restrictions in Brockton

Water Quality related

- Phosphorus loads, blue green algae blooms
- Bacteria – potential impact of high water levels on septic systems
- Beach closures
- Flow reversal
- Water quality degradation
- No dedicated source of funding for water quality testing for the Ponds

Watershed Management Optimization Support Tool (WMOST)

- Accounting tool for water
- Identify goals
- Evaluate integrated management practices
 - Stormwater
 - Drinking water
 - Wastewater
 - Land conservation
- Optimize costs while finding solutions

How much water is there and who is using it?

Notes:
 Units are million gallons per day
 Values are average annual reported values for 2000 through 2004 as summarized in WMA tool
 Private users are households on private well water and users with withdrawals less than 100,000 gallons per day

Welcome to the Model My Watershed simple water-balance simulator. See how changes in the amount of rainfall, the surfaces on which the rain falls and the texture of the soil change where the water goes. To begin, decide how much rain will fall by using the slide bar on the upper right. Then select the land-cover type where the rain will fall. Finally, pick a soil type. The coarsest soils (sandy soils) are on the left and the finest soils (clay loam) are on the right. As the simulation runs, follow where the water flows. Also, look at the column in the center that shows how much water goes in each direction.

i Warning! This combination produces too much runoff! Excess runoff is a problem because, when too much water runs over the land, it can cause flooding, can erode soil and can carry other contaminants into the stream. This results in unclear water that can kill animals in the stream and make it unsafe to drink.

Where is the rainfall going?

DAILY WATER BUDGET MODEL

Precipitation: 0.5 in

Land Cover: High Intensity Residential

Soil Type: Sandy Clay

The right panel shows a selection interface for the water budget model. It includes a precipitation slider set to 0.5 in, a land cover selection menu with 'High Intensity Residential' chosen, and a soil type selection menu with 'Sandy Clay' chosen. Below these are grids of icons for other options: Low Intensity Residential, High Intensity Residential, Commercial, Grassland, Forest, Turf Grass, Pasture, Row Crops, Sand, Loam, Sandy Clay, and Clay Loam.

i Warning! This combination does not allow for enough infiltration into the soil. Without enough groundwater recharge, plants will wilt and, possibly die and stream will not have enough water to flow between rainstorms to support the plants and animals that live there.

i Warning! This combination produces too much runoff! Excess runoff is a problem because, when too much water runs over the land, it can cause flooding, can erode soil and can carry other contaminants into the stream. This results in unclean water that can kill animals in the stream and make it unsafe to drink.

WMOST accounts for variation in weather, soils, land-use, and water extractions and returns in affecting the water balance.

What scenarios did we examine?

- Historic weather period covering both wet and dry years (2002 – 2006)
- Ranges in pond level (tradeoff between flooding costs and avail storage for water supply)
- Targets for pond outflow (passage for herring and other fish, cedar swamp protection)
- Timing and magnitude of water diversions from MP to Silver Lake

Which management practices did we consider?

- Water conservation
 - UnAccounted for Water status (leaks)
 - Reduced demand
- Alternative water sources
 - InterBasin Transfers from within Halifax
 - Substitution of Aquaria water source for Brockton
- Green infrastructure best management practices
- Aquifer Storage and Recharge

A green plastic rain barrel with a black lid, positioned next to a wooden fence and a grassy area.

Areas for least cost GI BMP placement for increasing water supply and outflows*

Sand & gravel, high density (322 acres)
residential or commercial land (61 acres)

*Other factors may influence final selections

Tradeoff between available water storage for supply and flooding costs

Example scenarios at 53 ft maximum pond level and cost

- The 25th percentile of historic (unimpacted) streamflows (5.58 cfs) can be maintained with water level range of 52.0 to 53.0 ft if:
 - Halifax demand maintained at 2009-2013 levels
 - Brockton diversions are eliminated entirely
 - **Green infrastructure stormwater BMPs** are implemented on 14 acres of developed land
 - Infrequent deficits are allowed (3 days, 109 million gallons total)
 - Estimated annual cost*:
 - Water supply: \$483,284 (\$16,526 less than historic 2002-2006 period of record)
 - Flooding (estimated building damages**): \$20,601

* Includes both annualized capital costs and operations and maintenance

** Based on generic FEMA flood depth-cost curves in HAZUS

Example scenarios at 53.5 ft maximum pond level and cost

- The 25th percentile of historic (unimpacted) streamflows (5.58 cfs) can be maintained with water level range of 52.0 to 53.5 ft if:
 - Halifax demand maintained at 2009-2013 levels
 - Brockton diversions are eliminated entirely
 - Estimated annual cost*:
 - Water supply: \$466,514 (\$33,296 less than historic 2002-2006 period of record)
 - Flooding costs (buildings**): \$84,889

OR

* Includes both annualized capital costs and operations and maintenance

** Based on generic FEMA flood depth-cost curves in HAZUS

Example scenarios at 53.5 ft maximum pond level and cost

- The 25th percentile of historic (unimpacted) streamflows (5.58 cfs) can be maintained with water level range of 52.0 to 53.5 ft if:
 - Halifax demand maintained at 2009-2013 levels
 - Brockton diversions are maintained at 2009-2013 levels minus the amount required to bring leaks down to Water Mgt Act requirements (reduce UAW by 1.6% to 10%)
 - Green infrastructure stormwater BMPs are implemented on 270 acres of developed land
 - Aquifer Storage and Recharge is implemented (\$\$\$)
 - Estimated annual cost: \$9.6 million

OR

Example scenarios at 53.5 ft maximum pond level and cost

- The 25th percentile of historic (unimpacted) streamflows (5.58 cfs) can be maintained with water level range of 52.0 to 53.5 ft if:
 - Halifax demand maintained at 2009-2013 levels
 - Brockton diversions are maintained at 2009-2013 levels minus the 3 MGD capacity of the Aquaria desalination plant to supply water to Brockton
 - **Green infrastructure stormwater BMPs** are implemented on 53 acres of developed land
 - Some water is transferred to MP within Halifax but from outside the MP watershed (“interbasin transfer”)
 - Infrequent deficits occur (2 days, 50.6 million gallons total)
 - Estimated annual cost:
 - Water supply: \$529,645 (\$28,469 more than historic 2002-2006 period of record)
 - Flooding costs (buildings**): \$84,889

Summary

- The Monponsett Ponds system is highly constrained, with a very tight operating range
- Competing water uses generate tradeoffs
- 25th percentile of unimpaired flows to Stump Brook could be met (but with occasional water deficits) based on historic climate period with wet and dry years for pond level range of 52 to 53.0 or 53.5 ft
- Green infrastructure stormwater BMPs a common least-cost solution in scenarios tested

Next steps

- Consider effect of management actions on water quality as well as quantity
- Need for a regional integrated water management solution
 - Potential effect of GI BMPs in upper Taunton in moderating flooding costs
 - Potential effect of GI BMPs in upper Taunton on groundwater supply (reducing need for diversions)
- Other tools available to guide implementation
 - EPA BMP siting tool (parcel-specific)
 - OptiTool with WMOST v3 (water quality protection)*

* Available next year
